Random Group Variance Estimators for Survey Data with Random Hot Deck Imputation

Jun Shao¹ and Qi Tang²

Random hot deck imputation is often applied to survey data with nonresponse. One of the popular methods for variance estimation without nonresponse is the random group method, which has to be adjusted when it is applied to imputed data. One such kind of adjustment is reimputing nonrespondents in each random group. We show that the random group method with reimputation produces asymptotically unbiased and consistent variance estimators for estimated population totals. As a special case of our general result, the random group variance estimator for the case of no nonresponse is asymptotically unbiased and consistent, a result that has not been documented although the random group method is frequently used in applications. We also show how to apply a shortcut random group method, which reduces the computational complexity due to reimputation, and establish the asymptotic unbiasedness and consistency of the resulting variance estimators.

Key words: Hot deck imputation; nonresponse; variance estimation; random group; reimputation; shortcut.

1. Introduction

Nonresponse exists in most survey problems. Hot deck imputation is a very popular method to impute nonrespondents by respondents from the same variable (Kalton and Kasprzyk 1986; Rubin 1987). In this article, we focus on ignorable nonresponse, random hot deck imputation, and the most basic survey sampling design, the stratified probability proportional to size sampling design considered as a single stage sampling design or the first stage of a multi-stage sampling design.

Variance estimation is an important element in sample surveys. The random group method (Wolter 2007) is a popular replication method used in many economic surveys in agencies such as the U.S. Census Bureau and the U.S. Bureau of Labor Statistics. Replication methods require more computation, but have the advantages of (1) requiring no separate theoretical derivations of a variance formula for each problem, which can be difficult or messy; (2) programming ease in complex situations; (3) using a unified recipe for various problems; and (4) to some degree, robustness against violations of models/assumptions.

Although most imputation methods are designed so that treating imputed values as observed data and applying formulas for the case of no nonresponse leads to approximately valid survey estimators (such as estimators of population means or totals), treating imputed values as observed data and applying variance formulas for the case of no nonresponse produces substantial underestimation of variances when the proportion of nonrespondents is appreciable. Thus, various adjustment methods are proposed in the literature for imputed data. For replication methods, Rao and Shao (1992) proposed to apply an adjustment to every replicate to address the effect of nonresponse and imputation. Shao (2001) showed that the Rao-Shao adjustment is equivalent to re-imputing every replicate, i.e., performing the same imputation procedure in every replicate using data in the replicate.

For replication methods such as the jackknife, balanced repeated replication, and bootstrap, the resulting variance estimators after re-imputation have been shown to be asymptotically consistent (e.g., Rao and Shao 1992; Shao and Sitter 1996; Shao et al. 1998). However, the same result for the random group variance estimator with re-imputation adjustment has not been established prior to our study. In fact, even the consistency of the random group variance estimator in the case of no nonresponse has not been documented. The first purpose of this article is to show the asymptotic unbiasedness and consistency of the random group variance estimator with re-imputation for data with non-respondents imputed by random hot deck. Of course, our result includes the case of no nonresponse as a special case.

Since re-imputation has to be applied to every replicate, the computation of a replication variance estimator can be time-consuming and computer-intensive. Some shortcut replication methods have been considered to reduce the computational complexity (see Moore 2006; Thompson and Yung 2006; Haziza et al. 2010). These shortcut methods vary with the imputation method and/or the replication method. The second purpose of this article is to study the construction of a shortcut random group variance estimator that reduces the computational complexity due to re-imputation and is still asymptotically unbiased and consistent.

The formulas for the random group variance estimator with re-imputation and its shortcut version are introduced in Section 2. Asymptotic properties of variance estimators are studied in Section 3. In Section 4, the random group variance estimation method is applied to a data set for illustration. Proofs of the results are provided in the Appendix.

2. The Random Group Method and Its Shortcut

Let $P$ be a finite population containing units indexed by $i$ and $S$ be a sample taken from $P$ according to some sampling design. According to the sampling plan, survey weights $w_i$, $i \in S$, are constructed so that the Horvitz-Thompson type estimator $\hat{Y} = \sum_{i \in S} w_i y_i$ is unbiased (with respect to the repeated sampling) for the population total $Y = \sum_{i \in P} y_i$, where $y_i$ is a variable (item) of interest.

A replication method starts with the construction of $K$ replicates. When there is no nonresponse, the data set (including the survey weight) is $\{(y_i, w_i), i \in S\}$. The $k$th replicate is then $\{(y_i, w_i^{(k)}), i \in S\}$, $k = 1, \ldots, K$. Note that only the survey weight $w_i$ is changed to $w_i^{(k)}$. For the random group method (Wolter 2007), we randomly form $K$ groups...
of the same or nearly the same size. The union of the $K$ groups is $S$ and the $k$th replicate is \{$(y_i, g^{(k)}_i w_i), \ i \in S$\}, where

$$g^{(k)}_i = \begin{cases} K & \text{if } i \text{ is in group } k \\ 0 & \text{if } i \text{ is not in group } k \end{cases}$$

Let $\hat{Y}^{(k)} = \sum_{i \in S} g^{(k)}_i w_i y_i$, $k = 1, \ldots, K$. The random group variance estimator for $\hat{Y}$ is

$$v = \frac{1}{K(K-1)} \sum_{k=1}^{K} \left( \hat{Y}^{(k)} - \frac{1}{K} \sum_{j=1}^{K} \hat{Y}^{(j)} \right)^2$$

Forming random groups has to ensure that the original sampling design is reflected within the groups (Wolter 2007). If the original sampling design is one-stage stratified sampling with $H$ strata, for example, then each group should contain all $H$ strata. If cluster sampling (either one-stage or multi-stage) is used, then clusters should be considered as units in forming random groups and the random group variance estimator should be used when the number of clusters is large.

### 2.1. Imputation and Reimputation

Let $R = \{i \in S, \ i \text{ is a respondent}\}$ and $N = \{j \in S, \ j \text{ is a nonrespondent}\}$. For simplicity, we call $y_i$ a respondent when $i \in R$ and $y_j$ a nonrespondent when $j \in N$. When there are nonrespondents, we usually create $L \geq 1$ imputation cells such that the nonresponse probability in each imputation cell is nearly constant and then apply the random hot deck within each imputation cell. More specifically, a nonrespondent in an imputation cell is imputed by a respondent $y_i$ in the same imputation cell selected with probability proportional to $w_i$. After imputation, treating imputed values as observed data leads to the following estimator of the population total $Y$:

$$\hat{Y}_r = \sum_{i \in R} w_i y_i + \sum_{j \in N} w_j \tilde{y}_j = \sum_{i \in R} w_i y_i(1 + u_i) \quad (1)$$

where $\tilde{y}_j$ is the imputed value for a nonrespondent $y_j$, $u_i = \sum_{j \in N} w_j d_{ij}/w_i$, $d_{ij} = 1$ if the imputed value $\tilde{y}_j = y_j$ and $d_{ij} = 0$ otherwise. Under the assumption that the nonresponse probability is constant within each imputation cell, $\hat{Y}_r$ is consistent and asymptotically normal (see, e.g., Rao and Shao 1992).

Treating imputed values as observed data and applying the formula for the case of no nonresponse leads to a naive variance estimator given by

$$v_I = \frac{1}{K(K-1)} \sum_{k=1}^{K} \left( \hat{Y}^{(k)}_I - \frac{1}{K} \sum_{j=1}^{K} \hat{Y}^{(j)}_I \right)^2$$

with

$$\hat{Y}^{(k)}_I = \sum_{i \in R} g^{(k)}_i w_i y_i + \sum_{j \in N} g^{(k)}_j w_j \tilde{y}_j$$

However, $v_I$ underestimates the variance of $\hat{Y}_r$, because it treats imputed values as observed data. The reimputation method can be described as follows. An imputed value in
an imputation cell and the $k$th group is treated as a nonrespondent and is reimputed by a respondent $y_i$ in the same imputation cell and the $k$th group selected with probability proportional to $g_{ki} w_i$. The resulting estimator of $Y$ based on the $k$th group is

$$
\hat{Y}_{RI}^k = \sum_{i \in R} g_{ki} w_i y_i + \sum_{j \in N} g_{kj} w_j \tilde{y}_j
$$

where $\tilde{y}_j$ is the reimputed value. The key difference between $\hat{Y}_{RI}^k$ and $\hat{Y}_{I}^k$ is that the former uses the original imputed $\tilde{y}_j$ whereas the latter replaces $\tilde{y}_j$ by a reimputed value $\tilde{y}_j^k$ using the respondents in group $k$. The random group variance estimator with reimputation is given by

$$
v_{RI} = \frac{1}{K(K-1)} \sum_{k=1}^K \left( \hat{Y}_{RI}^k - \frac{1}{K} \sum_{j=1}^K \hat{Y}_{RI}^j \right)^2
$$

(3)

2.2. Shortcut

Since reimputation has to be carried out for every replicate, the computation of $v_{RI}$ in (3) can be quite complicated. A shortcut proposed in Moore (2006) can be described as follows. Note that each sampled unit $i \in S$ is associated with a “group label” $g_{ki}$ for forming the random groups. Instead of reimputing every replicate, we “impute” the group label $g_{ki}$ associated with a nonrespondent $y_j$ by $g_{k}^R$, the group label of the respondent used to impute $y_j$. Imputing the group label associated with a nonrespondent alters each replicate so that replicates have different sizes. This creates more variation among replicate estimators, which results in a variance estimator larger than the naive estimator $v_I$.

The shortcut replicate estimator based on the $k$th group is

$$\bar{Y}_S^k = \sum_{i \in R} g_{ki} w_i y_i + \sum_{j \in N} g_{kj} w_j \tilde{y}_j
$$

which is different from $\bar{Y}_I^k$ since $g_{ki}$ in $\bar{Y}_I^k$ is replaced by $g_{k}^R$. The shortcut random group variance estimator is

$$v_S = \frac{1}{K(K-1)} \sum_{k=1}^K \left( \bar{Y}_S^k - \frac{1}{K} \sum_{j=1}^K \bar{Y}_S^j \right)^2
$$

(4)

Note that

$$\bar{Y}_S^k = \sum_{i \in R} g_{ki} w_i y_i + (1 + u_i)
$$

For reimputation,

$$\bar{Y}_{RI}^k = \sum_{i \in R} g_{ki} w_i y_i + (1 + u_i^{(k)})
$$

where $u_i^{(k)} = \sum_{j \in N} K^{-1} g_{kj} w_j d_{ki}^{(k)} / w_i$, $d_{ki}^{(k)} = 1$ if $g_{ki} = g_{kj}$, and $d_{ki}^{(k)} = 0$ otherwise. Thus, $\bar{Y}_{RI}^k$ is computationally simpler than $\bar{Y}_{RI}^k$ because we do not need to compute $u_i^{(k)}$ for every $k$ or the reimputed values $\tilde{y}_j$.
Unfortunately, \( \nu_{S} \) may be inconsistent and seriously biased. To see this, we consider the special case of simple random sampling. Under simple random sampling, \( w_i = N/n \), where \( n \) and \( N \) are respectively the sample size and population size, and \( u_i = d_i \), the number of times respondent \( y_i \) is used to impute nonrespondents. If \( y_i \) is equal to a constant \( c \) for all \( i \), then we can estimate \( Y = cN \) perfectly by \( \hat{Y}_I = cN \) (as long as we have at least one observed value) and the asymptotic variance of \( \hat{Y}_I \) is 0. In this case, both \( \nu_I \) in (2) and \( \nu_{RI} \) in (3) are 0, since \( \hat{Y}_I(\kappa) = \hat{Y}_{RI}(\kappa) = cN \). On the other hand, a straightforward calculation shows that

\[
\hat{Y}_S(\kappa) = \frac{cN}{n} \sum_{l=1}^{L} \left( \sum_{i \in R_l} g_l^{(k)}(1 + d_i) - n \right)
\]

which is not 0 and can be arbitrarily large when \( c^2 \) is arbitrarily large. The problem is caused by the fact that, when \( y_i = c \) for all \( i \), \( \hat{Y}_S \) is not a prefect estimator, i.e., \( \sum_{i \in R} g_i^{(k)}(1 + d_i) \neq n \).

Thus, we propose an adjustment to force the shortcut replicate estimator to be prefect in the special case of \( y_i = c \) for all \( i \). Note that

\[
\hat{Y}_S^{(k)} = \frac{N}{n} \sum_{l=1}^{L} \sum_{i \in R_l} g_l^{(k)} y_i(1 + d_i)
\]

where \( R_l \) is the set of respondents in imputation cell \( l \), \( l = 1, \ldots, L \). Our adjustment is to divide each term in the previous sum by a factor

\[
a_{k,l} = \frac{1}{n_l} \sum_{i \in R_l} g_l^{(k)}(1 + d_i)
\]

where \( n_l \) is the sample size for imputation cell \( l \), i.e., the adjusted shortcut replicate estimator is

\[
\hat{Y}_S^{(k)} = \frac{N}{n} \sum_{l=1}^{L} \sum_{i \in R_l} g_l^{(k)} y_i(1 + d_i) / a_{k,l}
\]

In the special case of \( y_i = c \) for all \( i \),

\[
\hat{Y}_S^{(k)} = \frac{N}{n} \sum_{l=1}^{L} c n_l = cN
\]

Although this adjustment is derived under the special case of simple random sampling, our result in Section 3 shows that the same adjustment produces a consistent and asymptotically unbiased shortcut random group variance estimator in the case of unequal \( w_i \)'s.

Thus, in general, we define

\[
\hat{Y}_S^{(k)} = \sum_{l=1}^{L} \sum_{i \in R_l} g_l^{(k)} w_i y_i(1 + u_i) / a_{k,l}
\]
and the adjusted shortcut random group variance estimator

\[
V_{AS} = \frac{1}{K(K-1)} \sum_{k=1}^{K} \left( \frac{\hat{Y}_{S}^{(k)}}{k} - \frac{1}{K} \sum_{j=1}^{K} \hat{Y}_{S}^{(j)} \right)^2
\]

(5)

3. Asymptotic Unbiasedness and Consistency

We consider the asymptotic setting in which \( S \) is sampled from a sequence of finite populations, there is a fixed number of imputation cells, the response probability within each imputation cell is constant, and the number of sampled units in any imputation cell tends to \( \infty \). The estimator \( \hat{Y}_I \) in (1) is well-defined as long as there is at least one respondent in each imputation cell. The estimators \( \hat{Y}_I, \hat{Y}_{RI}, \) and \( \hat{Y}_S \) are well-defined as long as there is at least one respondent in each imputation cell and group \( k \). If the response probability in each imputation cell is positive, then asymptotically these conditions are satisfied and \( \hat{Y}_I, \hat{Y}_{RI}, \) and \( \hat{Y}_S \) are well-defined. From now on, all the expectations and variances are calculated conditional on the event that there is at least one respondent in each imputation cell and group. Thus, there are asymptotic expectations and variances.

For simplicity, we now assume that there is a single imputation cell \( (L = 1) \) and \( \mathcal{P}(i \in \mathcal{R}) = \pi \) for all \( i \in \mathcal{P} \). Since \( \hat{Y}_I = \sum_{l=1}^{L} \hat{Y}_I^{(l)} \), where \( \hat{Y}_I^{(l)} = \sum_{i \in \mathcal{R}_l} w_i y_i (1 + u_i) \) and \( \mathcal{R}_l \) is the set of respondents in imputation cell \( l \), all the results obtained are valid for the case of multiple imputation cells with a fixed \( L \) when \( \hat{Y}_I^{(l)} \)'s are independent or asymptotically independent.

3.1. Asymptotic Unbiasedness under Simple Random Sampling without Replacement

Under simple random sampling without replacement, \( w_i = N/n \) for all \( i \) and \( u_i \) in the formula of \( \hat{Y}_I \) equals to \( d_i \), the number of times unit \( i \) is used as a donor. Furthermore, \( P(d_{ij} = 1 | i \in \mathcal{R}, j \in \mathcal{N}, r) = 1/r \) and \( P(d_{ij}^{(k)} = 1 | i \in \mathcal{R}, j \in \mathcal{N}, r_k) = g_i^{(k)}/(K r_k) \), where \( r \) and \( r_k \) are random variables representing the numbers of respondents in the sample and in group \( k \), respectively. Let \( \delta_i \) be the indicator of whether unit \( i \) is a respondent, \( a = \{(N/n)\delta_i (1 + d_i), i \in P\}^t \), and \( y = (y_i, i \in P) \). Then \( \hat{Y}_I = a'y \) and

\[
\text{Var}(\hat{Y}_I) = y'E(aa')y - y'E(a)E(a')y
\]

Because missing is completely at random and imputation is random hot deck, components of \( a \) have the same distribution and, hence, \( E(aa') \) and \( E(a)E(a') \) are linear combinations of the \( N \times N \) identity matrix and the \( N \times N \) matrix with all ones. Also, \( E(aa') \) and \( E(a)E(a') \) do not depend on the \( y_i \)'s. Then

\[
\text{Var}(\hat{Y}_I) = \alpha y^2 + \beta \sum_{i \in P} y_i^2
\]

(6)

where \( \alpha \) and \( \beta \) are two constants not depending on the \( y_i \)'s. We now determine values of \( \alpha \) and \( \beta \) using two particular sets of \( y_i \)'s. When \( y_i = 1 \) for all \( i \in P \), \( \text{Var}(\hat{Y}_I) = 0 \) and result (6) becomes

\[
\alpha N^2 + \beta N = 0
\]

(7)
If all $y_i$'s are 0 except that $y_1 = 1$, then $\hat{Y}_1 = Nn^{-1}\delta_1(1 + d_1)$. $Y = 1$, $\sum_{i \in \mathcal{P}} y_i^2 = 1$, and result (6) becomes

$$\alpha + \beta = \text{Var}(Nn^{-1}\delta_1(1 + d_1))$$

Using result (21) in the Appendix, we obtain that

$$\alpha + \beta = \frac{N}{n} \left( 1 - \pi + \frac{1}{\pi} \right) + O(1) + O(N/n^2)$$

(8)

where $\pi$ is the response probability. From (6), (7), and (8), we obtain

$$\text{Var}(\hat{Y}_1) = \frac{N^2}{n} \left( 1 - \pi + \frac{1}{\pi} \right) S_N^2 + O(N) + O(N^2/n^2)$$

(9)

where

$$S_N^2 = \frac{1}{N} \sum_{i \in \mathcal{P}} (y_i - Y/N)^2$$

For $l = 1, \ldots, K$, let $a_l = \{(NK/n)\delta_\delta(1 + u_i^{(l)}), i \in \mathcal{P}\}'$ and let $\delta_\delta = 1$ if $y_i$ is a respondent in group $l$ and $\delta_\delta = 0$ otherwise. For the random group variance estimator with replication, by the exchangeability of group assignment

$$E(v_{RI}) = E\left( \frac{\hat{g}_{RI}^{(k)}}{K} \right) - E\left( \frac{\hat{g}_{RI}^{(h)}}{K} \right) = \frac{\gamma' E(a_h a'_k y) - \gamma' E(a_h a'_k y)}{K} = \gamma Y^2 + \eta \sum_{i \in \mathcal{P}} y_i^2$$

where $k \neq h$, $k, h \in \{1, \ldots, K\}$, and $\gamma$ and $\eta$ are two constants not depending on $y_i$'s. The last equality follows from the fact that $E(a_h a'_k)$ and $E(a_h a'_h)$ ($k \neq h$) are linear combinations of the $N \times N$ identity matrix and the $N \times N$ matrix with all ones. Again, by considering $y_i = 1$ for all $i \in \mathcal{P}$, we obtain

$$\gamma N^2 + \eta N = 0$$

(10)

by considering $y_i = 0$ for all $i$ except $y_1 = 1$, we obtain that

$$\gamma + \eta = \frac{N}{n} \left( 1 - \pi + \frac{1}{\pi} \right) + O\left( \frac{NK}{n^2} \right)$$

(11)

From (10) and (11), we obtain

$$E(v_{RI}) = \frac{N^2}{n} \left( 1 - \pi + \frac{1}{\pi} \right) S_N^2 + O\left( \frac{N^2 K}{n^2} \right)$$

(12)

Using the same technique, we obtain the following results for the two shortcut random group variance estimators

$$E(v_{AS}) = \frac{N^2}{n} \left( 1 - \pi + \frac{1}{\pi} \right) S_N^2 + O\left( \frac{N^2 K}{n^2} \right)$$

(13)

$$E(v_S) = \frac{N^2}{n} \left( 1 - \pi + \frac{1}{\pi} \right) S_N^2 + \left( -\pi + \frac{1}{\pi} \right) Y_n^2 + O\left( \frac{N^2}{n^2} \right)$$

(14)

Combining (9), (12), (13), and (14), we have the following result.
Suppose that \( S \) and \( \bar{Y} = Y/N \) are bounded. Then, under simple random sampling without replacement, \( v_{RI} \) and \( v_{AS} \) are asymptotically unbiased in the sense that

\[
\frac{n}{N^2} [E(v_{RI}) - \operatorname{Var}(\bar{Y})] \to 0 \quad \text{and} \quad \frac{n}{N^2} [E(v_{AS}) - \operatorname{Var}(\bar{Y})] \to 0
\]

when \( n \to \infty, n/K \to \infty, \) and \( n/N \to 0. \) The unadjusted shortcut random group variance estimator \( v_S \) is asymptotically biased in the sense that

\[
\frac{n}{N^2} [E(v_S) - \operatorname{Var}(\bar{Y})] = \left( -\pi + \frac{1}{\pi} \right) \bar{Y}^2 + O(1/n) + O(1/N)
\]

where \( \bar{Y} = Y/N. \)

### 3.2. Asymptotic Unbiasedness under Unequal Probability Sampling with Replacement

For unequal probability sampling, we consider sampling with replacement. Under unequal probability sampling without replacement, the derivation of a valid variance estimator may be too difficult or even impossible and, hence, at the stage of variance estimation, we treat \( S \) as a sample obtained with replacement. This may overestimate the variance when the original sampling design is without replacement and sampling fractions are not negligible. But it is often used in practice because of its simplicity when no valid variance estimator for without replacement sampling is available.

Let \( w_i = 1/(np_i), \) \( S^2_R = \sum_{i \in \mathcal{P}} \frac{y_i}{(np_i) - \bar{Y}}^2, \) \( P(d_{ij} = 1 | \mathcal{R}, i \in \mathcal{R}, j \in \mathcal{N}) = w_i/\sum_{i \in \mathcal{R}} w_i \) and \( P(d_{ij} = 1 | \mathcal{R}, i \in \mathcal{R}, j \in \mathcal{N}) = \frac{\psi}{w_i/\sum_{i \in \mathcal{R}} (f_i^{(k)} w_i)}, \) \( i, j \in \mathcal{P} \)

where \( p_i \) is the probability that \( y_i \) is sampled in each draw. We assume that

C1. \( M_1 N n < w_i < M_2 N n \) for all \( i \in \mathcal{P}, \) where \( M_1 \) and \( M_2 \) are constants;

C2. \( |\bar{Y}| = |Y/N| < M \) and \( S^2_R < M \) for a constant \( M > 0. \)

Condition C1 means that there is no unit that has extremely large or small inclusion probability. Under Conditions C1 and C2, it is shown in the Appendix that

\[
\frac{n}{N^2} \operatorname{Var}(\bar{Y}) = \frac{S^2_R}{\pi} + (1 - \pi) \left[ \bar{Y}^2 \left( \varphi + \frac{1}{\pi} (1 - 2\pi) \beta + 1 \right) \right]
\]

\[
+ \bar{Y}^2 \left( \frac{2\varphi}{\pi} + 2\alpha (\beta - 1) \right) + \frac{1}{N} \sum_{i \in \mathcal{P}} \frac{y_i^2}{\varphi} + o\left( \frac{1}{n} \right)
\]

where \( \alpha = \sum_{i \in \mathcal{P}} \gamma_i p_i, \) \( \beta = N^{-2} \sum_{i \in \mathcal{P}} 1/p_i, \) \( \varphi = N^{-2} \sum_{i \in \mathcal{P}} \gamma_i / p_i, \) and \( \psi = N \sum_{i \in \mathcal{P}} p_i^2. \) Under C1, \( \alpha, \beta, \varphi, \) and \( \psi \) are bounded. Hence, C1–C2 and result (15) show that \( \operatorname{Var}(\bar{Y}) \) is \( O(n^2/n). \)

Without loss of generality we assume that \( n/K \) is an integer, which is the “sample size” of each group (replicate). With reimituation, it is clear that, for a fixed group, \( Y_{RI}^{(k)} \) behaves like \( \bar{Y}_i \) with a sample size \( n/K. \) In particular, \( K^{-1} \operatorname{Var}(\bar{Y}_{RI}^{(k)}) = \operatorname{Var}(\bar{Y}_{RI}) + o(N^2/n). \)
It follows from exchangeability that, for $k \neq h$,

$$E(v_{RI}) = \frac{1}{K} \left[ E \left( \tilde{Y}_{RI}^{(k)} \right)^2 - E \left( \tilde{Y}_{RI}^{(k)} \tilde{Y}_{RI}^{(h)} \right) \right]$$

Let $E_G$ be the expectation taken under a fixed assignment of groups. Then, for $k \neq h$,

$$E \left( \tilde{Y}_{RI}^{(k)} \tilde{Y}_{RI}^{(h)} \right) = E_G \left( \tilde{Y}_{RI}^{(k)} \tilde{Y}_{RI}^{(h)} \right) = E_G \left( \tilde{Y}_{RI}^{(k)} \right) E_G \left( \tilde{Y}_{RI}^{(h)} \right) = E \left( \tilde{Y}_{RI}^{(k)} \right) E \left( \tilde{Y}_{RI}^{(h)} \right),$$

where the first and the last equalities are because of the exchangeability and the second equality is because data in different groups are independent and the imputation is also independently carried out in different groups. Hence, $\tilde{Y}_{RI}^{(k)}$ and $\tilde{Y}_{RI}^{(h)}$ are uncorrelated and

$$E \left( \tilde{Y}_{RI}^{(k)} \right) E \left( \tilde{Y}_{RI}^{(h)} \right) = \frac{1}{K} \sum_{i=1}^{K} \left[ E \left( \tilde{Y}_{ri}^{(k)} \right) E \left( \tilde{Y}_{ri}^{(h)} \right) \right] = \frac{1}{K} \frac{1}{n} \sum_{i=1}^{n} \left[ E \left( \tilde{Y}_{ri}^{(k)} \right) E \left( \tilde{Y}_{ri}^{(h)} \right) \right],$$

showing that $v_{RI}$ is asymptotically unbiased. For the adjusted shortcut estimators, $\tilde{Y}_{AS}^{(k)}$ and $\tilde{Y}_{AS}^{(h)}$ are not uncorrelated but the correlation converges to 0, i.e.,

$$\frac{n}{N^2K} \text{Cov} \left( \tilde{Y}_{S}^{(k)}, \tilde{Y}_{S}^{(h)} \right) = O(K^{-1}) \rightarrow 0, \quad k \neq h,$$

when $K \rightarrow \infty$ (see the Appendix). Then, for the adjusted shortcut random group variance estimator $v_{AS}$ in (5),

$$\frac{n}{N^2} E(v_{AS}) = \frac{n}{N^2K} \left[ E \left( \tilde{Y}_{S}^{(k)} \right)^2 - E \left( \tilde{Y}_{S}^{(k)} \tilde{Y}_{S}^{(h)} \right) \right]$$

$$= \frac{n}{N^2K} \left[ E \left( \tilde{Y}_{S}^{(k)} \right)^2 - E \left( \tilde{Y}_{S}^{(k)} \right) E \left( \tilde{Y}_{S}^{(h)} \right) \right] + O(K^{-1})$$

$$= \frac{n}{N^2K} \text{Var} \left( \tilde{Y}_{S}^{(k)} \right) + O(K^{-1}).$$

The form of $\text{Var} \left( \tilde{Y}_{S}^{(k)} \right)$ is not simple because of the shortcut and adjustment. In the Appendix, we derive a formula for $\text{Var} \left( \tilde{Y}_{S}^{(k)} \right)$, which leads to the following result.

**Theorem 2.** Under $C1-\text{C2}$, both $v_{RI}$ and $v_{AS}$ are asymptotically unbiased, i.e.,

$$\frac{n}{N^2} [E(v_{RI}) - \text{Var}(\tilde{Y}_I)] \rightarrow 0 \quad \text{and} \quad \frac{n}{N^2} [E(v_{AS}) - \text{Var}(\tilde{Y}_I)] \rightarrow 0$$

when $n/K \rightarrow \infty$ and $K \rightarrow \infty$.  

**3.3. Consistency**

To establish the consistency of $v_{RI}$ and $v_{AS}$, we focus on $v_{AS}$ because the discussion for $v_{RI}$ is similar. By exchangeability, $E \left( \tilde{Y}_{S}^{(k)} \right)$ does not depend on $k (k = 1, \ldots, K)$. Letting
\[\theta = E\left(\hat{Y}_S^{(k)}\right)\] and \[\bar{\theta} = K^{-1} \sum_{k=1}^K \hat{Y}_S^{(k)},\] we obtain that

\[
\frac{n}{N^2 v_{AS}} = \frac{n}{N^2 K(K-1)} \sum_{k=1}^K \left(\hat{Y}_S^{(k)} - \theta\right)^2 - \frac{n}{N^2(K-1)} (\theta - \bar{\theta})^2. \tag{18}
\]

The second term on the right-hand side of (18) converges to 0 in probability (see the proof of Theorem 3 in the Appendix). The first term on the right-hand side of (18) involves a sum of variables \(\left(\hat{Y}_S^{(k)} - \theta\right)^2, k = 1, \ldots, K\). If these variables are independent, then the consistency of \(v_{AS}\) follows from Khintchine’s law of large numbers and the fact that \(nN^{-2}K^{-1} E\left(\hat{Y}_S^{(k)} - \theta\right)^2 = nN^{-2} \text{Var}(\hat{Y}) + O(n^{-1}K) + O(n^{-1})\) (see the proof of Theorem 2 in the Appendix). Although \(\left(\hat{Y}_S^{(k)} - \theta\right)^2, k = 1, \ldots, K\), are not independent, the correlation among them converges to 0 and we can use a modified Khintchine’s law of large numbers (Lemma 1 stated in the Appendix) to establish the consistency of \(v_{RI}\) and \(v_{AS}\). The proof of the following result is given in the Appendix.

**Theorem 3.** When \(n/K \to \infty\) and \(K \to \infty\),

\[
\frac{n}{N^2 [v_{RI} - \text{Var}(\hat{Y})]} \to_p 0 \quad \text{and} \quad \frac{n}{N^2 [v_{AS} - \text{Var}(\hat{Y})]} \to_p 0, \tag{19}
\]

where \(\to_p\) is convergence in probability.

The asymptotic results require both \(n/K\) and \(K\) (the number of groups) to be large. In applications, constructing groups with a large \(K\) may not be easy when \(n\) is not very large. We can use the following idea proposed by Rao and Shao (1996). Suppose that we independently construct \(R\) sets of groups with the \(r\)th set containing \(K\) groups that result in the variance estimator \(v_{AS}^{(r)}\) according to formula (5). Then, we use \(v_{AS} = R^{-1} \sum_{r=1}^R v_{AS}^{(r)}\) as the adjusted shortcut variance estimator. This estimator is approximately as good as the \(v_{AS}\) with \(KR\) groups. \(v_{RI}\) with \(R\) sets of groups can be similarly obtained.

### 4. Empirical Results for the National Immunization Survey

The 2007 National Immunization Survey is used here to illustrate the application of the random group variance estimators and to examine their finite sample performance. This survey was conducted jointly by the National Center for Immunization and Respiratory Diseases and the National Center for Health Statistics (see http://www.cdc.gov/nis/data_files.htm). The survey design is stratified unequal probability sampling with 64 geological strata, each of which is used as an imputation cell. Duration of breast feeding (in days) is chosen to be the variable \(y\) of interest, because it has appreciable nonresponse. The population size \(N\) is 6,025,053 and the total sample size is 24,807. Ranges of the population sizes, sample sizes, sampling fractions, nonresponse rates, estimated stratum totals, and estimated stratum standard deviations over 64 strata are listed in Table 1.

Nonrespondents were imputed by random hot deck imputation within each imputation cell. Based on the imputed data set, four random group variance estimators, \(v_I, v_{RI}, v_S,\) and \(v_{AS}\), were computed for the estimated population total. Ten random groups were constructed within each imputation cell and grouping was independently repeated ten times (see the discussion at the end of Section 3). The results are listed in Table 2. From Table 2, \(v_i\) is much smaller than other variance estimates (e.g., 32% smaller than \(v_{RI}\)).
which indicates its underestimation. On the other hand, the shortcut estimate \( v_S \) is about 40\% larger than \( v_{RI} \), which suggests the overestimation of \( v_S \) as indicated by our analysis in Section 2. The adjusted shortcut estimate \( v_{AS} \) is close to \( v_{RI} \), both of which are shown to be asymptotically unbiased in Section 3.

To examine the finite sample performance of the four random group variance estimators, we conducted a simulation study based on a population generated using the observed data. Our simulation procedure is as follows.

1. Population. Within each stratum \( h = 1, \ldots, 64 \), population \( y \)-values are generated by first taking a probability proportional to survey weight sample of size equaling the original population size of stratum \( h \) with replacement from the respondents in the \( h \)-th stratum, and then adding a random noise to each generated population value. The random noises have mean 0 and standard deviation equal to \( 10^{-3} \) times the observed standard deviation within each stratum and are independent within and across strata.

2. Within the \( h \)-th population stratum generated in Step 1, draw a sample with replacement of the original sample size. The inclusion probability is proportional to the inverse of the original survey weight. Independent samples are obtained for \( h = 1, \ldots, 64 \).

3. Within each stratum, generate nonrespondents (missing completely at random) with the observed nonresponse rate. Respondents in different strata are obtained independently.

4. Perform random hot deck imputation for nonrespondents within each stratum and independently across strata.

5. Compute the estimated total \( \hat{Y}_I \) and random group variance estimates \( v_I, v_S, v_{AS}, \) and \( v_{RI} \) with \( K = 10 \) and \( R = 10 \).

6. Repeat steps 2–5 for 1,000 times. Compute \( V = \) the sample variance of the 1,000 \( \hat{Y}_I \)'s. Compute the averages of \( v_I, v_S, v_{AS}, \) and \( v_{RI} \) over 1,000 simulations, and their standard errors based on 1,000 simulations.

$V$: simulation sample variance of $Y_l$’s

The results are tabulated in Table 3. In theory, the simulation variance $V$ is close to the true variance when the simulation size is large. From Table 3, it is clear that $v_{AS}$, $v_{RI}$, and $V$ are very close to each other; the naive estimate $v_I$ is about 26% smaller than $V$; and $v_S$ is 41% larger than $V$. These results are consistent with our theory in Section 3 and support our conclusions based on the results in Table 2.

Appendix

Since $Y_l$, $i \in \mathcal{P}$, are sampled with replacement in Sections 3.2–3.3, to simplify the proofs, throughout, we view $\hat{Y}_l$, $v_I$, $v_S$, $v_{AS}$ and $v_{RI}$ as functions of $Y_1, \ldots, Y_n$ and $W_1, \ldots, W_n$, where $Y_l \ (l = 1, \ldots, n)$ denotes the random outcome from the $l$th sampling, which has discrete uniform distribution on $\mathcal{P}$, and $W_l$ is the associating weight of $Y_l$. The pairs $(Y_l, W_l)$, $l = 1, \ldots, n$, are independent of each other. Correspondingly, let $\mathcal{R} = \{l: Y_l$ is a respondent$\}$, and let $\mathcal{N} = \{m: Y_m$ is a nonrespondent$\}$, but $S$ is unchanged. Now, we introduce some additional notation. Define $U_l^{(j)} = (1 + u_i)g_l^{(j)}$, $U_l = (1 + u_i)$ and $Z_l = Y_lW_l$, where $u_i = \sum_{m \in \mathcal{N}} W_{ni}m/\sum W_l$ and $d_{lm} = 1$ if the imputed value $\hat{Y}_m = Y_{ni}$, 0 otherwise. Let $G = \{g_l^{(j)}, l = 1, \ldots, n, k = 1, \ldots, K\}$ denote the group assignment and $D = \{d_{lm}, l \in \mathcal{R}, m \in \mathcal{N}\}$ denote the imputation. Let $r = r_1 + \cdots + r_K$, where $r_k (k = 1, \ldots, K)$ denotes the number of respondents in the $k$th group. For any pair of event or variable $B$ and $C$, let $E_B|C$ and $\text{Var}_B|C$ be the conditional expectation and variance taken with respect to $B$ given $C$.

Proof of (8) Since $E[\delta_t(1 + d_{1})|\delta_1 = 0] = 0$, $E[\delta_t^2(1 + d_{1})^2|\delta_1 = 0] = 0$, and $P(\delta_1 = 1) = nN^{-1}\pi$,

$$
\text{Var}(n^{-1}N\delta_t(1 + d_{1})) = n^{-2}N^2E[\delta_t^2(1 + d_{1})^2] - n^{-2}N^2\{E[\delta_t(1 + d_{1})]\}^2
$$

$$
= n^{-1}N^2\pi E[\delta_t^2|\delta_t = 1] - \pi^2\{E[\delta_t(1 + d_{1})|\delta_t = 1]\}^2
$$

Recall that $d_{1}$ is the number of times $y_1$ is used as a donor to impute missing values. Conditional on $\delta_1 = 1$ and the number of respondents $r > 0$, $d_{1}$ has the binomial distribution with size $n - r$ and probability $r^{-1}$. Then, $\text{Var}(n^{-1}N\delta_t(1 + d_{1}))$ equals

$$
n^{-1}N\pi E[1 + r^{-1}(n - r)(2 + r^{-1}(n - 1))|\delta_t = 1] - \pi^2\{E[r^{-1}n|\delta_t = 1]\}^2
$$

(20)

Since we consider asymptotic expectations with $r > 0$, as $n \rightarrow \infty$, $E(r^{-1}|\delta_t = 1) = (n\pi)^{-1} + O(n^{-2})$ and $E(r^{-2}|\delta_t = 1) = (n\pi)^{-2} + O(n^{-3})$. Substituting these results into (20), we obtain that
\[
\text{Var}(n^{-1}N\delta_{i}(1 + d_{i})) = Nn^{-1}(1 - \pi + \pi^{-1}) + O(1) + O(Nn^{-2})
\]  
(21)

**Proof of (15)** We show (15) in three steps. First, let
\[A_n = nN^{-2}[E(\hat{Y}_i - E(\tilde{Y}_i))^2 - E(\hat{Y}_i - Y)^2] = -nN^{-2}[E(\tilde{Y}_i) - Y]^2\]  
(22)

To simplify (22), we have that
\[E(\tilde{Y}_i) = E(\sum_{i \in R} \alpha_i U_i)\]
which equals
\[E(n^{-1}Y) = n^{-1}N\alpha + O(n^{-1})\]

where the third equality is due to the Taylor expansion argument and Conditions C1–C2. Hence, (22) equals \(O(n^{-1})\).

Second, let \(B_n = nN^{-2}[E(\hat{Y}_i - Y)^2 - E(\tilde{Y}_i - Y)^2]\), which equals
\[nN^{-2}E[2E(\hat{Y}_i(\hat{Y}_i - Y)) + Y^2 - E(\tilde{Y}_i^2)] = B_{n1} + B_{n2}\]

where \(\hat{Y} = n^{-1}Y \sum_{i \in R}(1 + u_i)\), \(B_{n1} = 2nN^{-2}E[\hat{Y}_i(\tilde{Y}_i - Y)]\) and \(B_{n2} = nN^{-2}E[\tilde{Y}_i^2 - E(\tilde{Y}_i^2)]\). By Conditions C1–C2, we have
\[B_{n1} = 2(1 - \pi)\hat{Y}\{ -\pi^{-1}(\hat{Y} + \varphi) + \alpha\beta + \pi^{-1}(2 - \pi)\hat{Y}\} + O(n^{-1})\]
(23)

\[B_{n2} = -3\pi^{-1}(1 - \pi)(\beta - 1)\hat{Y}^2 + O(n^{-1})\]
(24)

Third, consider \(C_n = n/N^2E(\hat{Y}_i - \bar{Y})^2\). We have
\[C_n = \frac{n}{N^2}\left[ E\left\{\sum_{i \in R}(Z_i - n^{-1}Y)^2U_i\right\} + E\left\{\sum_{i \neq j \in R}(Z_i - n^{-1}Y)(Z_j - n^{-1}Y)U_iU_j\right\}\right] = \pi^{-1}S_N + (1 - \pi)\left\{N^{-1}\sum_{i = 1}^{N}\hat{Y}_i^2 - 2\hat{Y}\alpha + \hat{Y}^2\psi\right\} + O(n^{-1})\]
(25)

Since \(nN^{-2}\text{Var}(\hat{Y}_i) = A_n + B_{n1} + B_{n2} + C_n\), by (23)–(25) and the fact \(A_n = O(n^{-1})\), (15) is proved.
Proof of (16) For \( k = 1, \ldots, K \), let
\[
 f_k(t) = \{ a_k + (1 - t)E(a_k) \}^{-1} \left\{ t^{\hat{y}^{(k)}}_S + (1 - t)E(\hat{y}^{(k)}_S) \right\}
\]
where \( 0 < t < 1 \) with \( f_k(1) = \hat{y}^{(k)}_S \). By the Taylor expansion argument,
\[
f_k(1) = f_k(0) + f'_k(0) + 2^{-1} f''_k(0) \tag{26}
\]
where \( 0 < t < 1 \). Then, by the exchangeability of group assignment, \( \text{Cov} \{ f'_k(0), f''_k(0) \} = \text{Cov} \{ f'_h(0), f''_h(0) \} \) for \( k \neq h \), and this, together with the fact that \( f_k(0) \) and \( f'_0(0) \) are constant, gives:
\[
 \text{Cov} \left( \hat{y}^{(k)}_S, \hat{y}^{(h)}_S \right) = \text{Cov} \left( f_k(0) + f'_k(0) + 2^{-1} f''_k(0), f_h(0) + f'_h(0) + 2^{-1} f''_h(0) \right)
\]
\[
 = \text{Cov} \left( f'_k(0), f'_h(0) \right) + \text{Cov} \left( f''_k(0), f''_h(0) \right) + 4^{-1} \text{Cov} \left( f''_k(0), f''_h(0) \right) \tag{27}
\]
To simplify (27), we work on \( \text{Cov} \{ f'_k(0), f'_h(0) \} \) first. Since \( E(a_k) = 1 \), we have
\[
 \text{Cov} \{ f'_k(0), f'_h(0) \} = \text{Cov} \left( \hat{y}^{(k)}_S, \hat{y}^{(h)}_S \right) + \text{Cov}(a_k, a_h)
\]
\[
\times \left\{ E \left( \hat{y}^{(k)}_S \right) \right\}^2 - 2 \text{Cov} \left( \hat{y}^{(k)}_S, a_h \right) E \left( \hat{y}^{(k)}_S \right). \tag{28}
\]
Now, we calculate the three terms of the above separately. For the first term,
\[
 E \left( \hat{y}^{(k)}_S \hat{y}^{(h)}_S \right) = E \left\{ E_{G,D|R,S} \left( \sum_{\ell_i \neq \ell_h} Z_{\ell_i} Z_{\ell_h} U^{(k)}_{\ell_i} U^{(h)}_{\ell_h} \right) \right\} \tag{29}
\]
where the inside expectation of the right-hand side of (29) can be calculated by taking another conditional expectation:
\[
 E_{G,D|R,S} \left( U^{(k)}_{\ell_i} U^{(h)}_{\ell_h} \right) = \frac{r_k r_h K^2}{r (r - 1)} \left\{ 1 + \frac{2 \sum_{m \in \mathcal{N}} W_m}{\sum_{i \in \mathcal{R}} W_i} + \frac{\sum_{m_1, m_2 \in \mathcal{N}} W_{m_1} W_{m_2}}{\left( \sum_{i \in \mathcal{R}} W_i \right)^2} \right\}
\]
Plugging this back into (29), taking expectation with respect to \( S \) gives:
\[
 K^2 Y^2 E[r_k r_h | r(r - 1)]^{-1} \left[ 1 - (3n - 2r)n^{-2} + O_p(nr^{-2}) \right]
\]
Taking expectation of the above with respect to \( r_k, r_h \) given \( r \) and then taking expectation with respect to \( r \) yields:
\[
 E \left( \hat{y}^{(k)}_S \hat{y}^{(h)}_S \right) = Y^2 + O(n^{-1}N^2) \tag{30}
\]
By the exchangeability of group assignment, \( E\left(\frac{\bar{Y}_k}{\bar{Y}_h}\right) = \left\{ E\left(\bar{Y}_1\right)\right\}^2 \), which equals \( \{Y + O(n^{-1})\}^2 \). Then, this together with (30) and Condition C1 gives:

\[
\text{Cov}\left(\bar{Y}_k, \bar{Y}_h\right) = Y^2 [1 + O(n^{-1})] - [1 + O(n^{-1})]^2 = O(n^{-1}N^2)
\]

The calculation of the first term of (28) is now completed. Next, for the second term of (28), observe that:

\[
\sum_{k \neq h} \text{Cov}(a_k, a_h) + \sum_{k=1}^{K} \text{Cov}(a_k, a_h) = \text{Cov}\left(\sum_{k=1}^{K} a_k, \sum_{k=1}^{K} a_k\right) = \text{Var}\left(\sum_{k=1}^{K} a_k\right) = \text{Var}(K) = 0
\]

By the exchangeability of group assignment, we have that

\[
\text{Cov}(a_k, a_h) = -\{K(K - 1)\}^{-1} \sum_{k=1}^{K} \text{Var}(a_k) = -(K - 1)^{-1} \text{Var}(a_1),
\]

where \( \text{Var}(a_1) = \text{Var}\{E_{G|R,D,r}(a_1)\} + E\{\text{Var}_{G|R,D,r}(a_1)\} \) equals

\[
\text{Var}(Kr_1^{-1}) + E \left[ n^{-2} \sum_{i \in \mathcal{R}} (1 + d_i)^2 \left( K^2 r_1^{-1} - (Kr_1^{-1})^2 \right) \right]
\]

\[+ n^{-2} \sum_{i_1, i_2 \in \mathcal{R}} (1 + d_{i_1})(1 + d_{i_2}) \left( K^2 \frac{r_1(r_1 - 1)}{r(r - 1)} - (Kr_1^{-1})^2 \right) \]

\[= E\{(K - 1)r_1^{-1}\} + K^2 E \left[ \frac{r_1(r - r_1)}{r(r - 1)} \left\{ n^{-2} \sum_{i \in \mathcal{R}} (1 + d_i)^2 - r_1^{-1} \right\} \right] = O(n^{-1}K)
\]

Then, the second term in (28),

\[
\text{Cov}(a_k, a_h) \left\{ E\left(\frac{\bar{Y}_k}{\bar{Y}_h}\right) \right\}^2 = O(n^{-1}N^2)
\]

For the third term in (28), observe

\[
\sum_{k \neq h} \text{Cov}(\bar{Y}_k, a_h) + \sum_{k=1}^{K} \text{Cov}(\bar{Y}_k, a_h) = \text{Cov}\left(\sum_{k=1}^{K} \bar{Y}_k, \sum_{k=1}^{K} a_k\right) = \text{Cov}\left(\sum_{k=1}^{K} \bar{Y}_k, K\right) = 0
\]

By the exchangeability of group assignment, \( \text{Cov}(\bar{Y}_k, a_h) = (1 - K)^{-1} \text{Cov}(\bar{Y}_k, a_1) \) for \( k \neq h \), where
\[
\text{Cov}(\hat{Y}_S^{(i)}, a_i) = \text{Cov}\left\{ E_{G|R,S,D} \left( \hat{Y}_S^{(i)} \right), E_{G|R,S,D} \left( \hat{Y}_S^{(i)} \right), (a_i) \right\} + E\left\{ \text{Cov}_{G|R,S,D} \left( \hat{Y}_S^{(i)} \right), (a_i) \right\}
\]
\[
= \text{Cov} \left( Kr_I r^{-1}, Kr_I r^{-1} \sum_{l \in R} Z_l U_l \right) + E \left\{ \sum_{l \in R} Z_l \text{Cov}_{G|R,S,D} \left( U_l^{(i)}, (a_i) \right) \right\}
\]
\[
= E \left\{ \sum_{l_1, l_2 \in R} n^{-1} Z_{l_1} U_{l_1} (1 + d_{l_1}) \text{Cov} G_{R,S,D} \left( s^{(i)}_{l_1}, s^{(i)}_{l_2} \right) \right\} + Y(K - 1) E[r^{-1} + O(nr^{-3})]
\]
\[
= E \left[ K^2 r_I (r - r_1) \sum_{l \in R} Z_l U_l [n^{-1} (1 + d_l) - r^{-1}] \right] + Y(K - 1) E[r^{-1} + O(nr^{-3})]
\]
\[
= O(n^{-1}NK) + O(n^{-1}N).
\]

Hence, the third term of (28),
\[
\text{Cov}(\hat{Y}_S^{(i)}, a_i) E\left( \hat{Y}_S^{(i)} \right) = O(n^{-1}N^2).
\] (33)

With the fact that \( E\left( \hat{Y}_S^{(i)} \right) = O(N) \) combining (31), (32) and (33) gives, the first term in (27),
\[
\text{Cov}(f'_i(0), f'_h(0)) = O(n^{-1}N^2).
\]

Following similar argument, it can be shown that the remaining terms of (27) are of the same order as the first term. This implies,
\[
nN^{-2} K^{-1} \text{Cov}(\hat{Y}_S^{(i)}, \hat{Y}_S^{(h)}) = O(K^{-1}).
\]

Therefore, (16) is proved.

Proof of Theorem 2: Observe that \( E(v_{RI}) = K^{-1} \{ E(\hat{Y}_{RI})^2 - E(\hat{Y}_{RI}^2) \} \). Since, for \( k \neq h \), \( \hat{Y}_{RI}^{(k)} \) and \( \hat{Y}_{RI}^{(h)} \) are uncorrelated, \( nN^{-2} E(v_{RI}) = nN^{-2} K^{-1} \text{Var}(\hat{Y}_{RI}^{(k)}) \), which equals
\[
nN^{-2} K^{-1} \left[ \text{Var} \left\{ E_{S,R,D,G} \left( \hat{Y}_{RI}^{(k)} \right) \right\} + E \left\{ \text{Var}_{S,R,D,G} \left( \hat{Y}_{RI}^{(k)} \right) \right\} \right]
\]
\[
= nN^{-2} K^{-1} \text{Var}_{S,R,D,G} \left\{ \sum_{l \in R} Y_l W_l^* (1 + u_l^{(k)}) \right\},
\]
where \( W_l^* = K W_l \) and the equality follows from the fact that \( E_{S,R,D,G} \left( \hat{Y}_{RI}^{(k)} \right) \) and \( \text{Var}_{S,R,D,G} \left( \hat{Y}_{RI}^{(k)} \right) \) do not depend on \( G \). Conditional on group assignment \( G \), we view \( \hat{Y}_{RI}^{(k)} = \sum_{l \in R} Y_l W_l^* (1 + u_l^{(k)}) \) as a replicate of \( \hat{Y}_I = \sum_{l \in R} Y_l W_l (1 + u_l) \) calculated based on a random sample of size \( nK^{-1} \). Since (15) holds for all \( n \), we have:
\[
nN^{-2} E(v_{RI}) = nN^{-2} K^{-1} \text{Var}(\hat{Y}_{RI}^{(k)}) = nN^{-2} \text{Var}(\hat{Y}_I) + O(n^{-1}) + O(n^{-1}K),
\]
which means that \( v_{RI} \) is asymptotically unbiased when \( n^{-1}K \rightarrow 0 \).
Next, we show the asymptotic unbiasedness of $\nu_{AS}$. By (17), $nN^{-2}E(\nu_{AS})$ is asymptotically equivalent to $nN^{-2}K^{-1}\text{Var}(\bar{Y}_S^{(k)})$. Note that

$$nN^{-2}K^{-1}\left[ E\left( \bar{Y}_S^{(k)} - E\left( \bar{Y}_S^{(k)} \right) \right)^2 - E\left( \bar{Y}_S^{(k)} - Y \right)^2 \right] = O(n^{-1}K).$$  

Hence, to show the asymptotic unbiasedness of $\nu_{AS}$, it is sufficient to show $E\left( \bar{Y}_S^{(k)} - Y \right)^2$ is asymptotically unbiased for $\text{Var}(\bar{Y}_I)$. We have

$$nN^{-2}\left\{ K^{-1}E\left( \bar{Y}_S^{(k)} - Y \right)^2 - E(\bar{Y}_I - Y)^2 \right\}$$

$$= nN^{-2}K^{-1}E\left\{ \sum_{l \in R} a_k^{-2}(Z_l U_l^{(k)})^2 - K \sum_{l \in R} (Z_l U_l)^2 + a_k^{-2} \sum_{l_1, l_2 \in R} Z_{l_1} U_{l_1} Z_{l_2} U_{l_2} \right.$$  
$$- K \sum_{l_1, l_2 \in R} Z_{l_1} U_{l_1} Z_{l_2} U_{l_2} - 2Y \left( a_k^{-1} \sum_{l \in R} Z_l U_l^{(k)} - K \sum_{l \in R} Z_l U_l \right) + Y^2(1 - K) \left\} \right. $$

To simplify the above, we use the Taylor expansion argument similar to (26) to expand the three ratios with $a_k$ or $a_k^2$ as the denominator. For the first ratio $a_k^{-2}(Z_l U_l^{(k)})^2$, after expanding it to the first order term and taking the expectation, the residual part is already of order $O(n^{-2}N^2K^2)$, which multiplies with the factor $nN^{-2}K^{-1}$ converging to 0 when $n^{-1}K \to 0$. For $a_k^{-2} \sum_{l_1, l_2 \in R} Z_{l_1} U_{l_1}^{(k)} Z_{l_2} U_{l_2}^{(k)}$ and $a_k^{-1} \sum_{l \in R} Z_l U_l^{(k)}$, in order to obtain a residual part with order $O(n^{-2}N^2K)$, we expand them to high order Taylor series. Details are the following. By Condition C1 and the fact $E_{G.D|R.S}(a_k) = 1$,

$$E_{G.D|R.S}\left( a_k^{-2} \sum_{l_1, l_2 \in R} Z_{l_1} U_{l_1}^{(k)} Z_{l_2} U_{l_2}^{(k)} \right) = E_{G.D|R.S}\left( \sum_{l_1, l_2 \in R} Z_{l_1} Z_{l_2} U_{l_1}^{(k)} U_{l_2}^{(k)} \right)$$

$$+ 3E_{G.D|R.S}\left( \sum_{l_1, l_2 \in R} Z_{l_1} Z_{l_2} U_{l_1}^{(k)} U_{l_2}^{(k)} \right) \text{Var}_{G.D|R.S}(a_k)$$

$$- 2E_{G.D|R.S}\left( \sum_{l_1, l_2 \in R} Z_{l_1} Z_{l_2} \right) \text{Cov}_{G.D|R.S}(U_{l_1}^{(k)}, U_{l_2}^{(k)}, a_k) + O_p(n^{-2}K^2N^2)$$

and $E_{G.D|R.S}(a_k^{-1} \sum_{l \in R} Z_l U_l^{(k)})$ equals

$$E_{G.D|R.S}\left( \sum_{l \in R} Z_l U_l^{(k)} \right) + E_{G.D|R.S}\left( \sum_{l \in R} Z_l U_l^{(k)} \right) \text{Var}_{G.D|R.S}(a_k)$$

$$- E_{G.D|R.S}\left( \sum_{l \in R} Z_l \right) \text{Cov}_{G.D|R.S}(U_l^{(k)}, a_k) + O_p(n^{-2}K^2N)$$

$$= E_{G.D|R.S}\left( \sum_{l \in R} Z_l \right) \text{Cov}_{G.D|R.S}(U_l^{(k)}, a_k) + O_p(n^{-2}K^2N)$$
where \( \text{Cov}_{G,D,R,S}(U_{l_i}^{(k)}, a_k) \) equals:

\[
\frac{K}{n} \left\{ \sum_{m \in \mathcal{M}} W_m + (n - r - 1) W_l \sum_{m \in \mathcal{M}} W_m + (n - r) W_l \sum_{l \in \mathcal{L}} \frac{W_l}{\left( \sum_{l \in \mathcal{L}} W_l \right)^2} \right\} + O_p(r^{-2} K^2), \tag{38}
\]

and \( \text{Var}_{G,D,R,S}(a_k) = \frac{K}{n} \left\{ \frac{2(n - r)}{n - 1} \frac{\sum_{l \in \mathcal{L}} W_l^2}{\left( \sum_{l \in \mathcal{L}} W_l \right)^2} \right\} + O_p(r^{-2} K^2), \tag{39} \)

and \( \text{Cov}_{G,D,R,S}(U_{l_i}^{(k)}, U_{l_i}^{(h)}, a_k) \) equals:

\[
\frac{K}{n} \left\{ \sum_{m \in \mathcal{M}} W_m + \sum_{m_1 \neq m_2 \in \mathcal{M}} W_{m_1} W_{m_2} \left( \sum_{l \in \mathcal{L}} W_l \right)^2 \right\} + (W_l + W_{l_i}) \left\{ \frac{n - r}{\sum_{l \in \mathcal{L}} W_l} \frac{\sum_{m \in \mathcal{M}} W_m}{\left( \sum_{l \in \mathcal{L}} W_l \right)^2} + \frac{(n - r - 2) \sum_{m_1 \neq m_2 \in \mathcal{M}} W_{m_1} W_{m_2}}{\left( \sum_{l \in \mathcal{L}} W_l \right)^3} \right\} + O_p(r^{-2} K^2). \tag{40} \]

By plugging (37) and (36) into (35) and using (38)–(40) and the Taylor Expansion argument for simplification, we obtain, for \( k = 1, \ldots, K \),

\[
n N^{-2} K^{-1} E \left( \tilde{Y}_S^{(k)} - Y \right)^2 = n N^{-2} \text{Var} \tilde{Y}_l + O(n^{-1} K) + O(n^{-1}). \]

This together with (16) gives the asymptotic unbiasedness of \( v_{AS} \):

\[
n N^{-2} E(v_{AS}) = n N^{-2} K^{-1} \left\{ E \left( \tilde{Y}_S^{(1)} - Y \right)^2 + \text{Cov} \left( \tilde{Y}_S^{(1)}, \tilde{Y}_S^{(2)} \right) \right\} + O(n^{-1} K) \tag{41} \]

\[
= n N^{-2} \text{Var} \tilde{Y}_l + O(n^{-1} K) + O(K^{-1}) + O(n^{-1}).
\]

Theorem 2 is now proved.

**Lemma 1.** Let \( X_k^k, k = 1, \ldots, K \), be identically distributed positive random variables with a common mean \( \mu < \infty \) and a constant \( \text{Cov}(X_k^k, X_h^h) \) for \( k \neq h \) and any fixed
K. Assume that $\text{Cov}(X^k_X, X^h_X) \to 0$ as $K \to \infty$. Then, for any $\varepsilon > 0$,

$$
\lim_{K \to \infty} P \left( \left| \frac{1}{K} \sum_{k=1}^{K} X^k_X - \mu \right| > \varepsilon \right) = 0 \quad (42)
$$

Lemma 1 can be proved by slightly modifying the proof of Khintchine’s law of large numbers (see, e.g., Chung 1974, pp. 109–110) and using the fact that $\text{Cov}(X^k_X, X^h_X) \to 0$.

**Proof of Theorem 3.** The second term on the right-hand side of (18) converges to 0 in probability, because, by Chebyshev’s inequality, for any $\varepsilon > 0$ and $k \neq h$,

$$
P \left( \sqrt{n(\theta - \bar{\theta})^2} > \varepsilon \right) \leq \frac{nE(\theta - \bar{\theta})^2}{\varepsilon^2N^2(K - 1)}
$$

$$
= \frac{n\text{Var}(\bar{Y}^{(k)}_S)}{\varepsilon^2N^2(K - 1)K} + \frac{n\text{Cov}(\bar{Y}^{(k)}_S, \bar{Y}^{(h)}_S)}{\varepsilon^2N^2K}
$$

$$
= \frac{n\text{Var}(\bar{Y}^{(k)}_S)}{\varepsilon^2N^2(K - 1)K} + O(K^{-1})
$$

$$
\to 0
$$

when $K \to \infty$, where the second last equality follows from (16) and the last equality follows from $\text{Var}(\bar{Y}^{(k)}_S) = O(N^2K/n)$. It remains to show the first term on the right-hand side of (18) is consistent. For $k = 1, \ldots, K$, let $X^k_X = nN^{-2}(K - 1)^{-1}(\bar{Y}^{(k)}_S - 0)^2$.

Following similar argument for the proof of (16), it can be shown that $\text{Cov}(X^k_X, X^h_X) \to 0$ when $nK^{-1} \to \infty$ and $K \to \infty$. By Theorem 2, (15) and C1, $E(X^k_X)$ is bounded for all $k$.

Then, by Lemma 1, (42) holds. This, together with the proved fact $\lim_{K \to \infty} E(X^k_X) - nN^{-2}\text{Var}(\bar{Y}_I) = 0$ in Theorem 2, implies $v_{AS}$ is asymptotically consistent. Thus, Theorem 3 is proved.
